

Food Delivery App - Internship Project Report

Company: UCT

Project Type: Full Stack Web Application

1. Background

The food delivery system connects restaurants and customers through a digital platform. It allows users to browse restaurants, view menus, add items to cart, place orders, and track order status.

2. Problem Statement

Customers need a simple way to discover nearby restaurants, place food orders, and receive real-time order updates. Restaurants need a dashboard to receive and manage orders efficiently.

3. Objectives

- Build a responsive restaurant browsing interface.
- Implement cart and checkout flow.
- Store and retrieve order data from the backend.
- Show order status and estimated delivery time.
- Prepare a database schema for future expansion.

4. Design and Implementation

The project uses a Node.js and Express backend with static frontend files. Restaurant and menu data are served through API endpoints. Orders are saved in a JSON file for simplicity, while the database.sql file defines a relational schema for real deployment.

5. Features

- Restaurant listing with search
- Menu display for selected restaurant
- Add-to-cart and quantity update
- Checkout form
- Order creation and tracking
- Recent orders section

6. Result

The result is a functional starter project that can be uploaded to GitHub and demonstrated in an internship review. It provides a solid base for adding authentication, maps, driver tracking, payments, and admin features later.

7. Learnings

This project demonstrates frontend-backend integration, API design, state handling in JavaScript, and the basics of relational database planning.

Prepared for submission as a GitHub project with code and report.
